

ABSTRACT

A light handle of an illuminating light is provided which produces a directed beam of light in order to precisely orient and align the illuminating light on a work area. Preferably, a laser producing light source is incorporated within the handle housing, and the directed beam of laser light projects from the distal end of the light handle. The laser light source may be battery powered, or may be powered by a solar panel mounted to the light handle; the illuminating light providing sufficient light to power the solar panel. To maintain sterility in a surgical environment, a light handle cover may be mounted to the light handle. For non-sterile applications, the light handle may simply be attached to the illuminating light without the light handle cover.
